Accelerated Computing

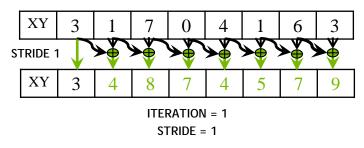

Module 10.2 – Parallel Computation Patterns (scan) A Work-inefficient Scan Kernel

Objective

- To learn to write and analyze a high-performance scan kernel
 - Interleaved reduction trees
 - Thread index to data mapping
 - Barrier Synchronization
 - Work efficiency analysis

A Better Parallel Scan Algorithm

- 1. Read input from device global memory to shared memory
- 2. Iterate log(n) times; stride from 1 to n-1: double stride each iteration

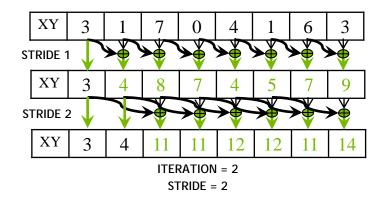

- Active threads *stride* to n-1 (n-stride threads)
- Thread *j* adds elements *j* and *j*-stride from shared memory and writes result into element j in shared memory
- Requires barrier synchronization, once before read and once before write

A Better Parallel Scan Algorithm

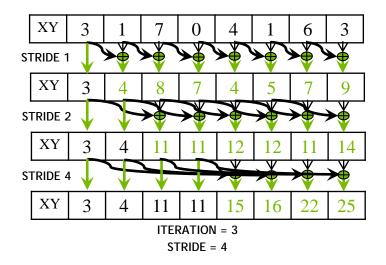

- 1. Read input from device to shared memory
- 2. Iterate log(n) times; stride from 1 to n-1: double stride each iteration.

A Better Parallel Scan Algorithm

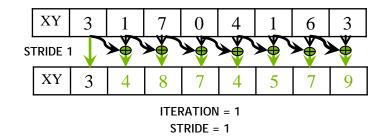

- 1. Read input from device to shared memory
- 2. Iterate log(n) times; stride from 1 to n-1: double stride each iteration
- 3. Write output from shared memory to device memory

Handling Dependencies

- During every iteration, each thread can overwrite the input of another thread
 - Barrier synchronization to ensure all inputs have been properly generated
 - All threads secure input operand that can be overwritten by another thread
 - Barrier synchronization is required to ensure that all threads have secured their inputs
 - All threads perform addition and write output

A Work-Inefficient Scan Kernel

```
__global__ void work_inefficient_scan_kernel(float *X, float *Y, int InputSize) {
__shared__ float XY[SECTION_SIZE];
int i = blockIdx.x * blockDim.x + threadIdx.x;
if (i < InputSize) {XY[threadIdx.x] = X[i];}
// the code below performs iterative scan on XY
for (unsigned int stride = 1; stride <= threadIdx.x; stride *= 2) {
  __syncthreads();
  float in1 = XY[threadIdx.x - stride];
  __syncthreads();
  XY[threadIdx.x] += in1;
}
__syncthreads();
If (i < InputSize) {Y[i] = XY[threadIdx.x];}</pre>
```

}

Work Efficiency Considerations

- This Scan executes log(n) parallel iterations
 - The iterations do (n-1), (n-2), (n-4),..(n-n/2) adds each
 - − Total adds: $n * log(n) (n-1) \rightarrow O(n*log(n))$ work
- This scan algorithm is not work efficient
 - Sequential scan algorithm does *n* adds
 - A factor of log(n) can hurt: 10x for 1024 elements!
- A parallel algorithm can be slower than a sequential one when execution resources are saturated from low work efficiency
